

A good local fit is not yet a retrieval explanation

Same rule: current query $\approx$ previous query + one shared shift per head

Largest query changes
Very little attention directly on color values

Strongest value-token attention
77-79% of attention on color-value tokens

Each panel changes four selected heads together. 32 discovery pairs; shifts fitted on the opposite fold.

All keys, values and remaining native computation stay live. Head selection used discovery measurements.

The additive rule was supplied; all fits reached the iteration limit. Failure does not yet separate fitting from missing state.

No lexical heldout results or native parameter-edit results are included. These tests do not establish a retrieval algorithm.
